	Weight	Elements	HD+ (100%)	HD	DI	CR	PA	PA-	NN
Approach	**60%**	**1) Data exploration leading to well informed approach.** **2) Identifying an adequate evaluation framework that is tailored to the problem.** **3) Well justified network architecture and objective.** **4) Hyper parameters selection strategy.** **5) Approach satisfies all the requirements and restrictions.**	Fulfils all req in HD. No further improvements are needed. **Solution demonstrate innovative elements** that goes beyond what is discussed in class.	Single network that predicts outputs using all the information. Efficient design process. **Appropriate use of transfer learning. Alternative ways of using the available information are explored and justified.** All of the following elements are done; **no issue in applying ML principles**: data exploration; network architecture and objectives; evaluation framework; hyper-parameter tuning. **Justifications are clear and complete.**	Single network that predicts outputs using all the information. **Efficient design process.** All of the following elements are done; **no issue in applying ML principles**: Data exploration; network architecture and objectives; evaluation framework; Hyper parameter tuning. **Justifications are mostly clear** but few places where justifications are not adequate.	Single network that predicts outputs **using all the information.** All of the following elements are done, however, **there are minor gaps in** applying ML principles: Data exploration; network architecture and objectives; evaluation framework; Hyper parameter tuning. **Justifications are mostly clear** but some places where justifications are not adequate.	The neural network(s) developed **can make the required prediction**, but uses only part of the available information (e.g. a single frame). This caps the mark at PA regardless of other quality. Within that: **all four elements are present, with at most one major ML error** (data exploration; network architecture and objectives; evaluation framework; hyper-parameter tuning).	Incomplete approach that does not meet the minimum requirements for PA. **More than one of the following elements contains major ML errors**: data exploration; network architecture and objectives; evaluation framework; hyper-parameter tuning.	Not Completed or Does not adhere to requirements in specification.
Ultimate Judgment, performance & Analysis	**25%**	**1) Analysis of the model and the outputs using suitable methods.** **2) Make a clear ultimate judgment.** **3) Rationale behind the ultimate model is clear and considers all the aspects.** **4) Limitations of the model identified.** **5) Realistic assessment of the model's chance of success at deployment.**	Fulfils all requirements in HD. No further improvements are needed. Limitations are clearly discussed. Deployment readiness is assessed with exceptional rigour; the conclusion (positive or negative) is realistic and fully supported by evidence.	Ultimate judgment is established, and all aspects are taken into consideration. All the justification is easy to follow. An excellent attempt at evaluating the ultimate model is made; no improvements are needed. Analysed the model's output using independent test data. Deployment readiness is assessed realistically and is well supported by evidence.	Ultimate judgment is established, and all aspects are taken into consideration. All the justification is easy to follow. A sufficient attempt at evaluating the ultimate model is made, a few places where minor improvements are needed. Analysed the model's output using independent test data. Deployment readiness is assessed realistically, with only minor gaps.	Ultimate judgment is established, but not all aspects are taken into consideration. A few places where the justification is hard to follow. A sufficient attempt at evaluating the ultimate model is made, at least one place where major improvement is needed. Analysed the model's output using independent test data. A reasonable assessment of deployment readiness, but not all factors are considered.	An ultimate judgment is made but not justified adequately. Analysis present but only trivial techniques used. Deployment readiness is assessed superficially or over-optimistically.	No valid ultimate judgment: the analysis is absent, or relies on a leaky in-distribution evaluation that does not support the claims.	Not Complete
Part B(Executive summary)	**15%**	**1) A clear, actionable recommendation on the client's plan to ship the model as-is.** **2) Every point is grounded in evidence from the student's own Part A analysis.** **3) Appropriate breadth of risk: technical, operational, and safety / accountability.** **4) Concise, point-form, and pitched for a busy, non-technical executive audience.**	Fulfils all requirements in HD. No further improvements are needed. Some evidence on independent (outside given dataset) data is provided.	A clear, well-judged recommendation. Every key risk is grounded in specific evidence from the student's own Part A results. Technical, operational and safety / accountability dimensions are all considered. Concise and well pitched for an executive reader.	A clear recommendation. Most points are grounded in Part A evidence, with only minor gaps. The main risk dimensions are covered. Concise and appropriately pitched, with at most minor lapses.	A recommendation is made and mostly supported by Part A evidence, but some points are generic or one risk dimension is thin. Mostly concise and appropriately pitched, but focus or format slips in places.	A recommendation is present but largely unsupported by the student's own evidence, or too narrow (e.g. model accuracy only). Limited engagement with real deployment risk, or poorly pitched / over-long.	No clear recommendation, or the advice is unsupported and superficial. Does not engage with the risks of the deployment.	Not completed, or does not adhere to the requirements in the specification.
